2025 Sustainability and Impact Narrative

BlueMesa Sustainable Packaging LLC

Searchable native-text report. This file tests direct PDF text reading rather than OCR or table extraction.

Company and reporting boundary

BlueMesa Sustainable Packaging LLC manufactures recyclable paper-fibre food packaging at one facility in Sharjah Industrial Area. The reporting period is calendar year 2025. The organisational boundary includes production, sanitation, company-controlled onsite fuel and purchased electricity. Supplier production, employee commuting and customer disposal are excluded.

Nature of green contribution

The company manufactures moulded paper-fibre packaging intended to substitute selected plastic packaging formats. The contribution is supported by product specifications and delivery records. No universal claim is made for products without an identified customer baseline.

Water performance

Water consumption was 9,100 m3 in 2025 compared with 9,300 m3 in 2024. Production output was 3,100,000 finished units. Water intensity was therefore 2.94 litres per finished unit, compared with 3.21 litres per unit in the baseline year. The boundary covers production and sanitation water.

Greenhouse-gas emissions

Total GHG emissions were 238.0 tCO2e in 2025. This combines company-controlled Scope 1 fuel and location-based Scope 2 electricity. The 2024 baseline was 271.0 tCO2e. GHG intensity was 0.077 kgCO2e per finished unit. The values are management estimates and are not presented as externally assured.

Waste, circularity and customer effect

Resource use and recovery

Total waste generated was 142,000 kg during 2025. Waste recycled or reused was 65,320 kg, producing a waste diversion rate of 46 percent. Waste sent to disposal was 76,680 kg. The waste boundary includes production offcuts, rejected fibre products and general site waste. Diversion is measured by mass accepted for recycling or internal reuse divided by total waste generated.

Customer environmental effect

Buyer demand for lower-impact packaging increased in 2025. Customer pilot evidence exists, but full lifecycle verification has not been completed. The platform should therefore retain the distinction between demonstrated deployment and estimated future impact.

Operational transition

The proposed investment combines a high-efficiency moulding line with onsite solar. Production growth may offset part of the absolute energy reduction, so both total consumption and intensity must be monitored.

Cross-document reconciliation test

This management narrative records annual electricity consumption as 705,000 kWh for 2025. The utility statement is the authoritative meter record and reports 690,000 kWh for the same facility and period. The difference is deliberately retained so the evidence workspace can flag and resolve a real cross-document conflict rather than silently selecting a value.

Additional environmental information

The facility recorded 38 employee-led environmental improvement suggestions during 2025, of which 14 entered operational trials. This is useful organisational context but is not a defined environmental performance criterion.

A separate supplier note states that recycled input increased by 11 percent but does not identify a baseline year, measurement boundary or supporting quantity. It is intentionally incomplete and should remain contextual rather than becoming a scored performance value.

Evidence limitations

The reported figures are fictional demonstration data. Absolute consumption must be interpreted with production output, baseline trends and operational boundaries. Projected benefits are not counted as achieved results. Certification, permit and project-finance claims require their own supporting records.
