2025 Sustainability and Impact Narrative

TerraPack Circular Industries LLC

Searchable native-text report. This file tests direct PDF text reading rather than OCR or table extraction.

Company and reporting boundary

TerraPack Circular Industries LLC manufactures recyclable paper-fibre food packaging at one facility in Dubai Industrial City. The reporting period is calendar year 2025. The organisational boundary includes production, sanitation, company-controlled onsite fuel and purchased electricity. Supplier production, employee commuting and customer disposal are excluded.

Nature of green contribution

The company replaces selected single-use plastic food containers with moulded products containing recovered paper fibre. Environmental contribution is demonstrated through recycled-content purchasing records, production records and customer delivery records rather than inferred from the company name.

Water performance

Water consumption was 5,200 m3 in 2025 compared with 5,600 m3 in 2024. Production output was 2,400,000 finished units. Water intensity was therefore 2.17 litres per finished unit, compared with 2.55 litres per unit in the baseline year. The boundary covers production and sanitation water.

Greenhouse-gas emissions

Total GHG emissions were 96.0 tCO2e in 2025. This combines company-controlled Scope 1 fuel and location-based Scope 2 electricity. The 2024 baseline was 151.0 tCO2e. GHG intensity was 0.040 kgCO2e per finished unit. The values are management estimates and are not presented as externally assured.

Waste, circularity and customer effect

Resource use and recovery

Total waste generated was 84,000 kg during 2025. Waste recycled or reused was 65,520 kg, producing a waste diversion rate of 78 percent. Waste sent to disposal was 18,480 kg. The waste boundary includes production offcuts, rejected fibre products and general site waste. Diversion is measured by mass accepted for recycling or internal reuse divided by total waste generated.

Customer environmental effect

Two food-service customers completed pilots in 2025. Customer records indicate replacement of conventional plastic trays in defined product lines. Avoided-impact claims are not converted to tonnes of emissions because a verified customer baseline is not yet available.

Operational transition

Management approved a rooftop solar and closed-loop process-water project supported by a supplier quotation, implementation schedule and internal contribution. Expected savings remain projections until commissioning and post-project measurement.

Cross-document reconciliation test

This management narrative records annual electricity consumption as 408,000 kWh for 2025. The utility statement is the authoritative meter record and reports 410,000 kWh for the same facility and period. The difference is deliberately retained so the evidence workspace can flag and resolve a real cross-document conflict rather than silently selecting a value.

Additional environmental information

A voluntary habitat project established 1,250 square metres of native planting beside the facility. This biodiversity-related measure sits outside the current scored metric catalog and should be retained as source-linked additional context for later governance review.

A separate supplier note states that recycled input increased by 11 percent but does not identify a baseline year, measurement boundary or supporting quantity. It is intentionally incomplete and should remain contextual rather than becoming a scored performance value.

Evidence limitations

The reported figures are fictional demonstration data. Absolute consumption must be interpreted with production output, baseline trends and operational boundaries. Projected benefits are not counted as achieved results. Certification, permit and project-finance claims require their own supporting records.
